

FIELD OF THE INVENTION

The present invention relates generally to pet identification devices, and, more particularly to a method for making a double sided, metal Rabies I.D. tag in an electronic **engraving machine** capable of inscribing data on both sides whereby one side of the I.D. tag has inscribed personal contact information alongwith the name of the pet, and the other side has inscribed the rabies information.

BACKGROUND OF THE INVENTION

Many identification devices have been designed with various functions to aid in the retrieval of a lost pet, and they have been widely described in the Prior Art. See for example U.S. Pat. Nos. 6,502,060; 6,283,065; 6,003,473; 5,752,335; 5,690,365; 5,355,839; 4,137,660; 4,091,766; 3,805,427; 3,585,743; 3,020,658; 2,893,143; 1,657,250. The above patents, in some disclose pet identification tags or systems which solve the problem of identifying a lost pet and fail to disclose pertinent Rabies vaccination information especially if the lost pet has bitten, scratched, or endangered the life of a human. And, even though the animal's owner can be located by the rabies tag the animal still must be impounded by authorities for a period of time until necessary medical information of the pet can be determined by veterinary records to determine if the pet is safe to release to the owner. Or, the patents above which can electronically record such data are so expensive that pet owners are not willing to purchase them for their pets. And, the problem in general, with standard

Rabies tags most veterinary clinics issue, which come in an agreed upon shape for that particular year, is that there is not enough room on the tag to inscribe personal information alongwith vaccination data. Nor, are most Veterinarians skilled with the precision of jewelry craftsmen in inscribing words on metal tags, and due to the lack of this skill it was impractical if not impossible for Veterinarians or their assistants to conceive of attempting such a feat. And, due to a lack of skill and sophistication in the use of engraving tools, Veterinarians and their assistants would not attempt such an inscription. Therefore, veterinary clinics have relied upon purchasing pre-stamped, with an identification code, metal Rabies tags from which they can record the name of the pet and the Rabies vaccination in a computer, book, or journal. And, sometimes this recorded information is the only means of identifying for the owner a pet if it becomes lost. Often, veterinary clinics are burdened by the costs of purchasing more pre-stamped metal tags than they will issue for a given year.

The present invention provides a method for making a double sided, metal Rabies I.D. tag with an **electronic engraving** machine capable of inscribing data on both sides whereby one side of the I.D. tag has inscribed personal contact information alongwith the name of the pet, and the other side has inscribed the rabies vaccination information. And, the cost of such an I.D. tag made using the present invention is very inexpensive to the pet owner making it a very desirable option.

Those skilled in the prior art of electronic reproduction technology hav

limited its use to inscribing jewelry, novelty tags, and trinkets, being totally unaware of its potential use in the field of veterinary medicine. And, any method for producing a double sided, metal Rabies identification tag has been unknown to those skilled in the prior art.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a method for producing a double sided, metal Rabies I.D. tag, whereby a Veterinarian or a veterinarian assistant can easily inscribe both sides of a blank metal tag using a programmed computer system with a keyboard connected to an electronic engraving machine capable of such a task. The programmed computer system stores all pertinent Rabies data and I.D. tag numbers issued so that data does not have to be re-entered for each new I.D. tag, and the new I.D. tag is made with next sequential number in the series. The method of the present invention solves the following problems that are encountered daily in veterinarian clinics: 1.) the decision to I.D. tag becomes a very passive decision in that the pet's owner can receive the I.D. tag immediately and does not have to wait for several days for an I.D. tag to be shipped off to a company to be inscribed and returned in the mail before affixing it to their pet's collar. 2.) a pet does not have to wear additional tags for identification that jangle together causing a noise problem for the pet's owner. 3.) when a lost pet is found tracing its owner can be accomplished in a relatively short time by simply using the contact information on the reverse side of the I.D. tag to reunite the pet with its owner instead of having to research

the Rabies data on tag and sourcing out the pet's owner which can take several hours. 4.) Veterinarians can inscribe a blank I.D. tag on a per need basis and do not have a costly supply of pre-ordered I.D. tags left over at the end of the year.

The Humane Association did a study showing that animals with a metal I.D. tag resulted in a 90% return rate.
